

1 *Appendix G*

2  
3 *Determination of Energy Prices for the Approved Residential Rate.*

4  
5  
6 Having determined that the service charges should remain the same and that the 1<sup>st</sup>  
7 energy block should be set at 1000 KWh per Billing Period, the Board set the 1<sup>st</sup> energy  
8 block and run-out block energy prices subject to the following considerations:

- 9
- 10 1. Prices be such that the approved revenue requirement could be earned over the 12  
11 months of the test year,
  - 12 2. Progress be made towards eliminating the declining block rate,
  - 13 3. The intra-class subsidies and surcharges should be as small as possible, subject to  
14 the concern for rate shock.

15  
16 The revenue sufficiency issue (Item 1) was examined by using the 5 years of billing  
17 determinant data in evidence to make separate estimates for:

- 18 A. The number of service charges likely to be billed in the test year, by linear  
19 extrapolation of the 5 year trends for urban, rural and seasonal customers. The  
20 trend variable for each group was calculated by computing the number of billing  
21 months each invoice represented, rounded to 1 in the case of invoices containing  
22 from 1 to 45 billing days and rounded to the nearest integer month otherwise.
- 23 B. The 5-year average of the annual fraction of residential energy sales to urban,  
24 rural and seasonal customers groups.

1 C. The 5-year average fraction of sales made to each group that were made in a 1<sup>st</sup>  
2 energy block of 1000 KWh per Billing Period.

3

4 The extrapolated estimates for the number of service charges in the test year were  
5 multiplied by the approved charges to determine the contribution of service charge  
6 revenue to residential class revenue. The relevant data and the estimates appear in Table  
7 G.1.

8

9 The average annual energy fraction estimates were applied to the forecast energy sales  
10 for the test year to determine the anticipated split between urban, rural and seasonal sales.

11 The split between 1<sup>st</sup> and run-out energy blocks was applied to each of these groups' total  
12 sales and summed to find the total 1<sup>st</sup> and run-out block energy sales to the residential  
13 rate class for the test year. The relevant data and estimates for total and 1<sup>st</sup> block energy  
14 sales are shown in Table G.2. The proof of revenue for the residential class is provided  
15 in Table G.3

16

17

### 18 Customer Impact

19 The Board was concerned with the impact that the proposed and approved rates would  
20 have on customers. It therefore spent considerable time and effort to deliberate on this  
21 matter.

22

1 The billing determinants for each customer for the period of five fiscal years ending on  
2 March 31, 2005 were available in evidence and used for this purpose. The Board used  
3 this database to calculate the monthly bills for customers under the existing, proposed and  
4 approved rates. The monthly bills of all customers that had received a full year of service  
5 were then aggregated to form their annual cost under each of the three rates. These annual  
6 costs were used to calculate the percentage increase for each customer under the  
7 proposed rate and under the approved rate. This percentage increase in annual costs was  
8 used as the fundamental measurement of customer impact during deliberations.

9

10 The resulting dataset provided more than 1.2 million separate measurements of customer  
11 impacts. This exceeds the number of customers because each full year of service resulted  
12 in a measurement. Some customers provide 5 years of data, others 4, 3, 2, and 1 year of  
13 data. Using multiple years of data means that the effect of natural weather variation  
14 between years is included in the “average” impact. It also means that the analysis accords  
15 greater weight to the increases experienced by long-term customers than it does to short-  
16 term customers, so the data were also examined on a year-by-year basis to confirm that  
17 each year had a similar characteristics and they could be legitimately averaged for  
18 analysis.

19

20 The large number of measurements meant that they could not be examined individually,  
21 so the Board used two approaches to examine the measurements collectively:

- 22 1. Grouping customers by their annual energy use, and
- 23 2. Grouping customers by the increase in annual cost they experience.

Grouped Customer Impact by Annual Energy Use

In this approach, customers are assigned to a group based on a their annual energy use and the percentage change in cost for the group is examined. While this facilitates consideration of customer size in relation to cost impact, it must be appreciated that each customer in such a group can experience a cost increase that is different from that of the group as a whole.<sup>1</sup> As a consequence, one must look at more than the mean rate increase for the group to fully appreciate the impact on customers in the group.<sup>2</sup> This method also suffers from the fact that it does not directly indicate how many customers are subjected to a particular cost increase.

The customer impact using this approach is depicted in Figures G.1 and G.2, for the proposed and approved rates, respectively. The illustrations are limited to customers using up to 60,000 KWh per year. This includes 99.5% of the measurements. Each figure provides three curves. These depict the maximum, average, and minimum annual cost increases borne by the customers in each group. The vertical bars through the average curves represent the dispersion about the centre of the group. Longer bars indicate that

---

<sup>1</sup> For an extreme example, consider two urban customers, each using 12,000 KWh per year. Both would be in the same group because they have the same annual consumption. Customer A uses their energy evenly throughout the year, 1000 KWh per month, and would pay \$1217.28 per year under the existing rate and \$1316.88 per year under the approved rate, an 8.2% increase. Customer B uses their energy in 1 month, and pays \$1031.70 per year under the existing rate and \$1250.88 under the approved rate, a 21.2% increase.  
<sup>2</sup> The median or middle value of the rate increases for the group and/or the modal or most probable value will generally be better estimates of the groups' characteristics and must be used if the mean deviates appreciably from them. The dispersion of the group about the mean/median must also be examined.

1 customers are widely disbursed between the maximum and minimum curves; shorter bars  
2 indicate that the customers are clustered close to the average curves.<sup>3</sup>

3

#### 4 *Proposed Rate*

5 Figure G.1 indicates that 99.5% of customers would have experienced cost increases  
6 ranging from 10.4% to 17.9% under the proposed rate. The dispersion is largest in the  
7 range of 10,000 to 20,000 KWh per year consumption, but generally indicates that  
8 customers are clustered about the mean, or average, curve. The extreme values can  
9 deviate significantly from the average. While the mean increase for customers using  
10 10,000 KWh per year is 10.7% (the median is 10.5%), one customer in that group  
11 experiences a 16.7% rate increase. Similarly, the mean and median increases for  
12 customers using 30,000 KWh per year are 14.7% and 14.6%, respectively, but one  
13 customer in that group experiences only a 10.9% rate increase.

14

#### 15 *Approved Rate*

16 Figure G.2 indicates that 99.5% of customers would have experienced cost increases  
17 ranging from 0% to 24.3% under the approved rate. The dispersion is largest at 15,000  
18 KWh per year consumption and becomes smaller only slowly as customer size increases.  
19 This indicates that customers are disbursed more widely about the average than in the  
20 proposed rate. The extreme values also deviate significantly from the average. While the  
21 mean increase for customers using 10,000 KWh per year is 7.9% (median is 7.7%), one  
22 customer in that group experiences a 19.5% rate increase. Similarly, the mean and

---

<sup>3</sup> The error bars represent  $\pm 3$  standard deviations.

1 median increases for customers using 30,000 KWh per year are 16.3% and 16.2%,  
2 respectively, but one customer in that group experiences only a 7.6% rate increase.

3

#### 4 Grouped Customer Impact by Increase in Annual Cost

5 In this approach, customers are assigned to groups based on the increase in the annual  
6 costs they experience and the distribution of increases across all customers is examined.

7 This has the benefit of directly indicating the fraction of customers subject to a given cost  
8 increase. It also reveals the dispersion and the nature of deviations between the mean,  
9 median and modal values for the rate designs as whole, rather than just sub-groups. The  
10 drawback of this approach is that it provides no indication of the customer characteristics  
11 that give rise to the cost increase.

12

13 The results of this analysis are provided in Figure G.3. Note the highly skewed  
14 distributions for both the proposed and approved rates. This is a good indication the  
15 mean rate increase for the class as a whole may be misleading to individual customers.

16 The mean, median, modes and ranges of the distributions are also given in the  
17 illustration.

18

19 The proposed rate increase would have resulted in a year-round customer cost increases  
20 averaging 12.4%. The median increase under the proposed rate was 12.0%, indicating  
21 that half of the customers would have experienced a higher increase than that, and half  
22 would have experienced a lower increase. The most likely rate increase that a customer

1 would experience is the mode, 10.6%. Cost increases under the proposed rate ranged  
2 from 10.4% to 19.8%.

3

4 The approved rate increase should result in a customer cost increases averaging 10.95%.

5 The median increase under the approved rate should be 10%, with half of the increases

6 being either above or below that value. The most likely rate increase is 7.8%, and the

7 increases range from 0% to 29.6%.

8

9 Figure G.4 presents essentially the same data as Figure G.3, but does so using the

10 cumulative distributions of rate increases. This indicates the fraction of customers that

11 are exposed to a particular range of cost increases. For example, the median is found by

12 moving horizontally from the point marked 50% on the vertical axis until a distribution

13 curves is reached, and then moving vertically down to the horizontal axis. Figure 4 also

14 illustrates that roughly 70% of customers should experience rate increases below 13.5%

15 under either rate design.

16

17 Figure G.5 presents the distributions of cost increases for each fiscal year. Note that the

18 shape of the distribution is constant from year to year. The relatively small variations on

19 a year-over-year basis suggest that the average of all years (Figure G.3) provides a

20 reasonable basis for evaluating the expected impact on customers.

21

22

1 *Residential Customer Impact Summary*

2 The impact of the changes in approved residential rate can be summarized as follows:

- 3 • Small customers that use electricity more-or-less uniformly throughout the year  
4 will experience the smallest increases in their bills.
- 5 • Large customers with usage that varies significantly over the year will experience  
6 the largest increases in their bills.
- 7 • The approved rate should result in lower cost increases than the proposed rate for  
8 approximately 70% of customers and higher cost increase for 30% of customers.
